

Solution

NDB1007: Practical class 5

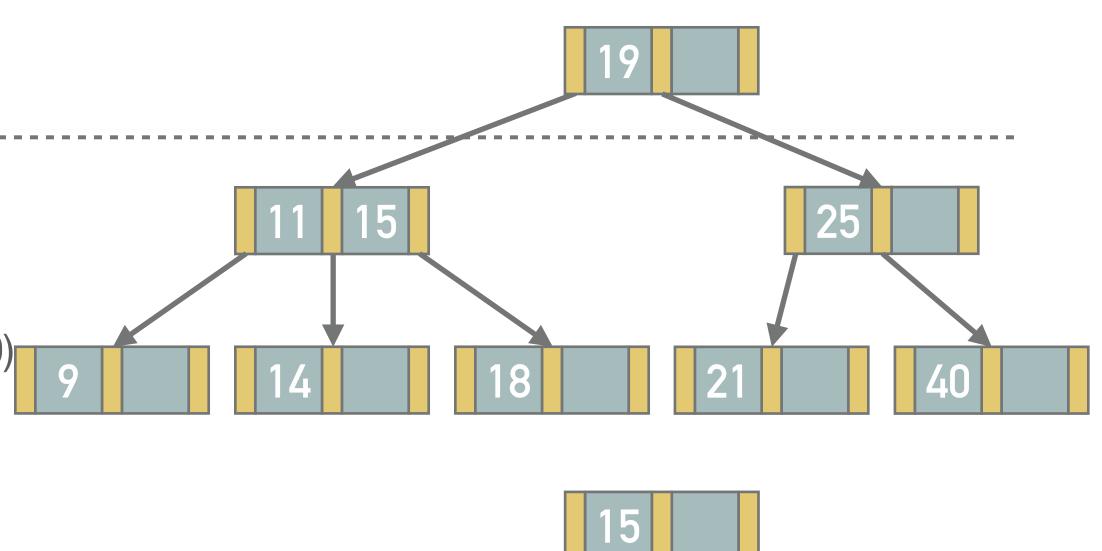

Exercise 5.6 (Solution)

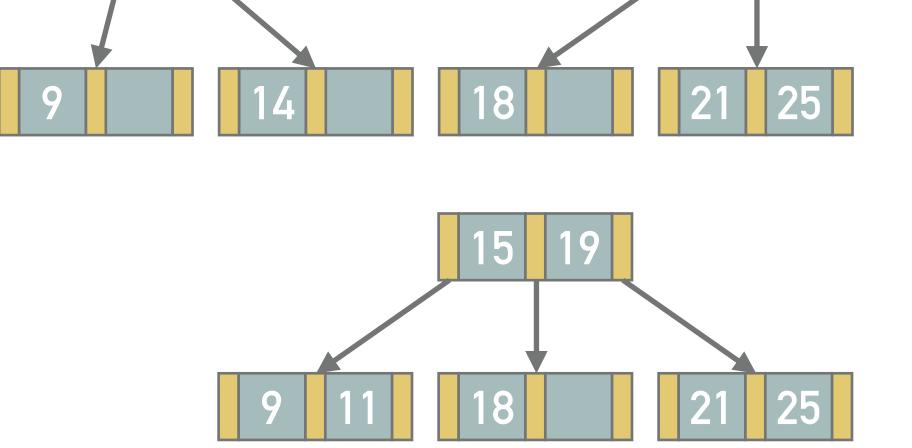

- Insertion of key 11
 - * Key 11 is less than 19, i.e., we navigate to the left (leaf) node (9, 15)
 - * After an attempt to insertion, the leaf (9, 11, 15) contains too many keys, a splitting occurs
 - * Key 11 goes to the parent (11, 19, 25) that also contains too many keys, i.e., additional splitting occurs and the tree height is increased
- Insertion of key 18
 - * Key 18 is less than 19, i.e., we navigate to the left node (11)
 - * Key 18 is greater than 11, i.e., we navigate to the right node (15)
 - * Key 18 goes to the leaf (15, 18)
- Insertion of 14
 - * Key 14 is less than 19, i.e., we navigate to the left node (11)
 - * Key 14 is greater than 11, i.e., we navigate to the right (leaf) node (15, 18)
 - * After the insertion, the leaf (14, 15, 18) contains too many keys, a splitting occurs
 - * Key 15 goes to the parent node (11, 15)

Exercise 5.6 (Solution Continued)

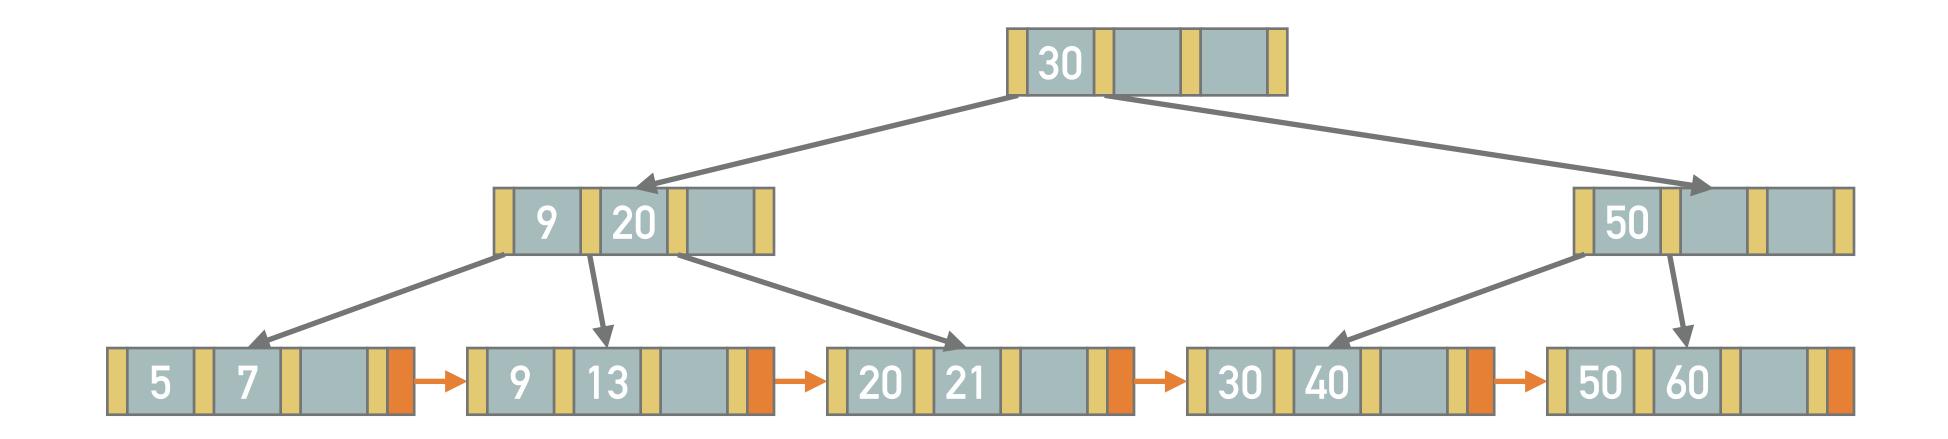

- Deletion of record with key 40
 - * Key 40 is greater than 19, i.e., we navigate to the right node (25)
 - * Key 40 is greater than 25, i.e., we navigate to the right (leaf) node (40)
 - * Key 40 is removed, but we have to merge nodes (empty) and (25)
 - * Parent node (empty) has too few keys, therefore we take key from the left sibling (19)
 - * Finally, taking a key from the left children (11, 15), 15 goes to the root node
- Deletion of record with key 14
 - * Key 14 is less than 15, i.e., we navigate to the left node (11)
 - * Key 14 is greater than 11, i.e., we navigate to the right (leaf) node (14)
 - * Key 14 is removed, causing the splitting of nodes (9) and (11)
 - * Finally, we have to merge nodes (15, 19) to establish a new root node

Exercise 5.12 (Solution)

- * The insertion of a record with key 40 splits the right lead node into nodes (20, 21) and (30, 40)
 - * The separating value 30 is inserted into the parent node where there is enough space
- * The insertion of a key 50 is trivial, it goes to the node (30, 40, 50)
- * The insertion of a key 60 splits the right leaf node into nodes (30, 40) and (50, 60)
 - * The separating value 50 is inserted into the parent node (9, 20, 30, 50) where it leads to the cascade split
 - * The parent is split to nodes (9, 20) and (50) while (30) foes to the root node

Exercise 5.17 (Solution)

 We can delete the record 15 while moving the record 20 to the neighboring node and modification of the split value

* The record with key 9 will be removed while moving the record with key 8 and modification of the split value

* The record with key 8 will be removed while moving the record with key 7 and modification of the split value

 Removing another record would lead to meging of the tree nodes into two
